

Remarks for model A in EPC:

Regarding the indication of human and automatic tasks I chose to represent them by connecting the model object "IT System" to functions that are performed automatically. This representation is suboptimal, as it does not tell the reader of the model if there is a human working ON the IT system to perform the task, or if it is the IT system ITSELF that performs the task in an automated manner.

Like model A in BPMN the last XOR gateway functions as both, loop, and decision as it allows the process flow to diverge into three different paths (the loop and two different ways).
